

Process & Decision Document

This project is a branching interactive story built in p5.js using multiple game states across separate files (start, game, win, lose, instructions). The player moves through a small decision tree where each choice affects a tracked stat called KARMA. Depending on the final KARMA value, different endings are unlocked (positive, neutral, or negative outcomes). The structure uses a router system in main.js to switch between screens and a story object in game.js to manage narrative nodes and choices. One design decision I made was to centralize all story branches inside a structured STORY object instead of writing multiple conditional statements. This made the code more scalable and easier to expand. It also allowed the karma stat tracking and ending resolution logic to remain clean and modular rather than being scattered across scenes.

I used GenAI to help restructure and debug the multi-file state management system and to refine the branching story logic.
